

Technical Decisions:

The use of Unity as the engine to contain the project LLM was always confirmed due to the availability of projects that allow for the easy integration of Ollama and Neocortex into Unity. It was then through careful manipulations of these projects that we were able to create the outcome we wanted. It is then through the use of other systems able to give it data that we were able to make both the quest system and the LLM work together through the use of a text file. In terms of performance ensuring that the LLM is not intensive upon the game scene were essential due to how intensive Local Models can become with the increase in parameters. Due to this and the Local Model only having to take the data given to it and combine it with the prompt we chose to use a smaller version of Llama 3.2 at 3B parameters.

Gameplay Impact:

In terms of impact upon the game the LLM is designed to enrich the gameplay experience by explaining why it is the player is searching for these items in the fetch quest. It has no impact on the actual gameplay and impacts the narrative reaction from the people doing the task.

Workflow Evaluation:

After the integration of the LLM the challenge came in the form of understanding how to get the data from the text file to the LLM to read it. The initial idea being that the text file would replace the input field the prompt for the AI's personality would be, however would in the moment felt like it would not solve the problem of the text chat input being empty and not giving data to the LLM. As such the input prompt for the AI was kept as it was and the text file would be copy pasted over to the text chat input and sent to the LLM.
